

# Package ‘RankProd’

June 13, 2025

**Version** 3.35.0

**Date** 2016-09-16

**Title** Rank Product method for identifying differentially expressed genes with application in meta-analysis

**Author** Francesco Del Carratore

<francesco.delcarratore@manchester.ac.uk>,  
Andris Jankevics <andris.jankevics@gmail.com>  
Fangxin Hong <fxhong@jimmy.harvard.edu>,  
Ben Wittner <Wittner.Ben@mgh.harvard.edu>,  
Rainer Breitling <rainer.breitling@manchester.ac.uk>,  
and Florian Battke <battke@informatik.uni-tuebingen.de>

**Maintainer** Francesco Del Carratore

<francescodc87@gmail.com>

**Depends** R (>= 3.2.1), stats, methods, Rmpfr, gmp

**Imports** graphics

**Description** Non-parametric method for identifying differentially expressed (up- or down- regulated) genes based on the estimated percentage of false predictions (pfp). The method can combine data sets from different origins (meta-analysis) to increase the power of the identification.

Apples	<i>Metabolomics data on spiked apples</i>
--------	---

---

## Description

A dataset of LC-MS features, obtained from twenty apples. The last ten apples are spiked with known compounds. This set provides a test case for biomarker selection methods: the task is to retrieve the true biomarker variables. The raw LC-MS data have been converted to CDF format and processed with XCMS to obtain the basepeaks.

## Usage

```
data(Apples)
```

## Value

The format is a list of four elements:

mz	the m/z values of the features (rounded)
rt	the retention times of the features
apples.data	a matrix containing the intensities in the individual samples
apples.data.vsn	a matrix containing the intensities after variance stabilization and normalization performed with the vsn package
Biom	the indices of the "true" biomarkers
apples.cl	numeric vector encoding which samples are part of the spiked class (code 1) and which ones are controls (code 0)

## Author(s)

Francesco Del Carratore

## References

P. Franceschi, D. Masuero, U. Vrhovsek, F. Mattivi and R. Wehrens: A benchmark spike-in data set for biomarker identification in metabolomics. *J. Chemom.* 26, 16-24 (2012)

arab

*Genomic Response to Brassinosteroid in Arabidopsis*

---

## Description

These data are from Affy ATH1 array experiments of genomic response to brassinosteroid in *Arabidopsis* conducted by two laboratories. The data set contains 500 random selected genes and 10 samples, 6 from lab 1 and 4 from lab 2. Data were pre-processed by RMA

## Usage

```
data(arab)
```

## Value

arab	matrix of gene expression levels of 500 genes from 10 samples, rows correspond to genes and columns to mRNA samples.
arab.cl	numeric vector encoding the treatment classes, 5 brassinosteroid-treated cases (code 1) and 5 control cases (code 0)
arab.gnames	character vector containing the AffyID of the 500 genes for the expression matrix arab
arab.origin	numeric vector encoding the origin of the samples, 6 samples from lab 1 (code 1) and 4 samples from lab 2 (code 2)

Microarray data from AtGenExpress (<http://arabidopsis.org/info/expression/ATGenExpress.jsp>)

---

golub	<i>A subset of the Gene expression dataset from Golub et al. (1999)</i>
-------	---

---

### Description

Gene expression data (500 genes and 38 tumor mRNA samples) from the leukemia microarray study of Golub et al. (1999). The original dataset contains 3051 genes

### Usage

```
data(golub)
```

### Value

golub	matrix of gene expression levels for the 38 tumor mRNA samples. Rows correspond to genes and columns to mRNA samples.
golub.cl	numeric vector encoding the tumor classes, 27 acute lymphoblastic leukemia (ALL) cases (code 0) and 11 acute myeloid leukemia (AML) cases (code 1).
golub.gnames	a matrix containing the names of the 500 genes for the expression matrix golub. The three columns correspond to the gene index, ID, and Name, respectively.

---

lymphoma	<i>Subset of the Intensity data for 8 cDNA slides with CLL and DLBL samples from the Alizadeh et al. paper in Nature 2000</i>
----------	---

---

### Description

8 cDNA chips from Alizadeh lymphoma paper

### Usage

```
data(lymphoma)
```

**Format**

lymphoma is an `exprSet` containing the data of 8 chips from the lymphoma dataset by Alizadeh et al. (see references). Each chip represents two samples: on color channel 1 (CH1, Cy3, green) the common reference sample, and on color channel 2 (CH2, Cy5, red) the various disease samples. See `pData(lymphoma)`. The 9216x16 matrix `exprs(lymphoma)` contains the background-subtracted spot intensities (CH1I-CH1B and CH2I-CH2B, respectively).

**Details**

The chip intensity files were downloaded from the Stanford microarray database. Starting from the link below, this was done by following the links *Published Data* -> *Alizadeh AA, et al. (2000) Nature 403(6769):503-11* -> *Data in SMD* -> *Display Data*, and selecting the following 8 slides:

lc7b019  
lc7b047  
lc7b048  
lc7b056  
lc7b057  
lc7b058  
lc7b069  
lc7b070

Then, the script `makedata.R` from the `scripts` subdirectory of this package was run to generate the R data object.

**Value**

lym.exp	8 cDNA chips from Alizadeh lymphoma paper
lynx	Is a time series with numbers of annual numbers of lynx trapping in Canada from 1821-1934. Taken from Brockwell & Davis (1991), this appears to be the series considered by Campbell & Walker(1977)

---

plotRP

*Graphical Display of the Rank Product/Sum analysis*

---

**Description**

Plot a graph of the estimated pfp vs the number of identified genes

**Usage**

`plotRP(x, cutoff=NULL)`

**Arguments**

x	the value returned by function RP, RPadvance, RSadvance, RankProducts or RP.advance
cutoff	The pfp threshold value used to select genes

**Value**

A graphical display of the estimated pfp vs number of identified genes, which is also the gene rank of its original rank product/sum across all comparison. If cutoff is specified, a horizontal line will be plotted on the graphic to indicate the position of the cutoff point, and all genes identified will be marked in red.

Two plots will be displayed, one for the identification of up-regulated genes in class 2, one for the identification of down-regulated genes in class 2

RandProd-internal

*Internal RankProd functions*

---

**Description**

Internal RankProd functions.

**Details**

These functions are not meant to be called directly by the user.

**Author(s)**

Fangxin Hong, <fhong@salk.edu> \ Rainer Breitling, <rainer.breitling@manchester.ac.uk>  
 \ Francesco Del Carratore, <francesco.delcarratore@postgrad.manchester.ac.uk> \ Andris  
 Jankevics, <andris.jankevics@gmail.com>

---

RankProducts

*Rank Product/Rank Sum Analysis*

---

**Description**

The function performs the Rank Product (or Rank Sum) method to identify differentially expressed genes. It is possible to do either a one-class or two-class analysis.

**Usage**

```
RankProducts(data, cl, logged = TRUE, na.rm = TRUE, gene.names = NULL,
plot = FALSE, rand = NULL, calculateProduct = TRUE, MinNumOfValidPairs = NA,
RandomPairs = NA, huge = FALSE, fast = TRUE, tail.time = 0.05)
```

**Arguments**

data	the data set that should be analyzed. Every row of this dataset must correspond to a gene
cl	a vector containing the class labels of the samples. In the two class unpaired case, the label of a sample is either 0 (e.g., control group) or 1 (e.g., case group). For one class data, the label for each sample should be 1
logged	if "TRUE" data have been previously log transformed. Otherwise it should be set as "FALSE"
na.rm	if "FALSE", the NA value will not be used in computing rank. If "TRUE" (default), the missing values will be replaced by the genewise median of the non-missing values. Gene with a number of missing values greater than "MinNumOfValidPairs" are still not considered in the analysis
gene.names	if "NULL", no gene name will be attached to the outputs, otherwise it contains the vector of gene names
plot	if "TRUE", plot the estimated pfp vs the rank of each gene
rand	if specified, the random number generator will be put in a reproducible state
calculateProduct	if calculateProduct="TRUE" (default) the rank product method is performed. Otherwise the rank sum method is performed
MinNumOfValidPairs	a parameter that indicates the minimum number of NAs accepted per each gene. If it is set to NA (default) the half of the number of replicates is used
RandomPairs	number of random pairs generated in the function, if set to NA (default), the odd integer closer to the square of the number of replicates is used
huge	if "TRUE" not all the outputs are evaluated in order to save space

<code>fast</code>	if "FALSE" the exact p-values for the Rank Sum are evaluated for any size of the dataset. Otherwise (default), if the size of the dataset is too big, only the p-values that can be computed in "tail.time" minutes (starting from the tail) are evaluated with the exact method. The others are estimated with the Gaussian approximation. If <code>calculateProduct="TRUE"</code> this parameter is ignored
<code>tail.time</code>	the time (default 0.05 min) dedicated to evaluate the exact p-values for the Rank Sum. If <code>calculateProduct="TRUE"</code> this parameter is ignored

### Value

A summary of the results obtained by the Rank Product (or Rank Sum) method.

<code>pfp</code>	Estimated percentage of false positive predictions (pfp), both considering up-regulated and downregulated genes
<code>pval</code>	Estimated p-values per each gene being up- and down-regulated
<code>RPs/RSs</code>	The rank-product/rank-sum statistics evaluated per each gene
<code>RPrank/RSrank</code>	rank of the Rank Product (or Rank Sum) of each gene in ascending order
<code>Orirank</code>	Ranks obtained when considering each possible pairing. In this version of the package, this is not used to compute Rank Product (or Rank Sum), but it is kept for backward compatibility
<code>AveFC</code>	Fold change of average expressions (class1/class2). log fold-change if data has been log transformed, original fold change otherwise
<code>allrank1</code>	Fold change of class 1/class 2 under each origin. log fold-change if data has been log transformed, original fold change otherwise
<code>allrank2</code>	Fold change of class 2/class 1 under each origin. log fold-change if data has been log transformed, original fold change otherwise
<code>nrep</code>	Total number of replicates
<code>groups</code>	Vector of labels (as <code>cl</code> )
<code>RandomPairs_ranks</code>	a matrix containing the ranks evaluated for each <code>RandomPair</code>

RP

*Rank Product Analysis*

---

## Description

The function performs the Rank Product method to identify differentially expressed genes. It is possible to do either a one-class or two-class analysis. This function has been kept only to guarantee backward compatibility, in fact the same results can be obtained by [RankProducts](#).

## Usage

```
RP(data, cl, num.perm = 100, logged = TRUE, na.rm = TRUE, gene.names = NULL,
  plot = FALSE, rand = NULL, huge = FALSE)
```

## Arguments

data	the function performs the Rank Product (or Rank Sum) method to identify differentially expressed genes. It is possible to do either a one-class or two-class analysis
cl	a vector containing the class labels of the samples. In the two class unpaired case, the label of a sample is either 0 (e.g., control group) or 1 (e.g., case group). For one class data, the label for each sample should be 1
num.perm	in this version of the package, this parameter is not used any more, but it is kept for backward compatibility
logged	if "TRUE" data have been previously log transformed. Otherwise it should be set as "FALSE"

<code>na.rm</code>	if "FALSE", the NA value will not be used in computing rank. If "TRUE" (default), the missing values will be replaced by the genewise median of the non-missing values. Gene with a number of missing values greater than 50% are still not considered in the analysis
<code>gene.names</code>	if "NULL", no gene name will be attached to the outputs, otherwise it contains the vector of gene names
<code>plot</code>	if "TRUE", plot the estimated pfp vs the rank of each gene
<code>rand</code>	if specified, the random number generator will be put in a reproducible state
<code>huge</code>	if "TRUE" not all the outputs are evaluated in order to save space

### Value

A summary of the results obtained by the Rank Product method.

<code>pfp</code>	estimated percentage of false positive predictions (pfp), both considering upregulated and downregulated genes
<code>pval</code>	estimated pvalues per each gene being up- and down-regulated
<code>RPs</code>	the Rank Product statistics evaluated per each gene
<code>RPrank</code>	rank of the Rank Product of each gene in ascending order
<code>Orirank</code>	ranks obtained when considering each possible pairing. In this version of the package, this is not used to compute Rank Product (or Rank Sum), but it is kept for backward compatibility
<code>AveFC</code>	fold changes of average expressions (class1/class2). log fold-change if data has been log transformed, original fold change otherwise
<code>allrank1</code>	fold change of class 1/class 2 under each origin. log fold-change if data has been log transformed, original fold change otherwise
<code>allrank2</code>	fold change of class 2/class 1 under each origin. log fold-change if data has been log transformed, original fold change otherwise
<code>nrep</code>	total number of replicates
<code>groups</code>	vector of labels (as cl)
<code>RandomPairs_ranks</code>	a matrix containing the ranks evaluated for each RandomPair

### Note

Percentage of false prediction (pfp), in theory, is equivalent of false discovery rate (FDR), and it is possible to be large than 1.

The function looks for up- and down- regulated genes in two separate steps, thus two pfps and pvalues are computed and used to identify gene that belong to each group.

This function is suitable to deal with data from a single origin, e.g. single experiment. If the data has different origin, e.g. generated at different laboratories, please refer RP.advance.

## Description

The function performs the Rank Product method to identify differentially expressed genes. It is possible to do either a one-class or two-class analysis. It is also possible to combine data from different studies (e.g. datasets generated by different laboratories. This function has been kept only to guarantee backward compatibility, in fact the same results can be obtained by [RankProducts](#).

## Usage

```

RPadvance(data, cl, origin, num.perm = 100, logged = TRUE, na.rm = TRUE,
gene.names = NULL, plot = FALSE, rand = NULL, huge = FALSE)

```

## Arguments

data	the data set that should be analyzed. Every row of this dataset must correspond to a gene
cl	a vector containing the class labels of the samples. In the two class unpaired case, the label of a sample is either 0 (e.g., control group) or 1 (e.g., case group). For one class data, the label for each sample should be 1
origin	a vector containing the origin labels of the samples. The label is the same for samples within one lab and different for samples from different labs.

num.perm	in this version of the package, this parameter is not used any more, but it is kept for backward compatibility
logged	if "TRUE" data have been previously log transformed. Otherwise it should be set as "FALSE"
na.rm	if "FALSE", the NA value will not be used in computing rank. If "TRUE" (default), the missing values will be replaced by the genewise median of the non-missing values. Gene with a number of missing values greater than 50% are still not considered in the analysis
gene.names	if "NULL", no gene name will be attached to the outputs, otherwise it contains the vector of gene names
plot	if "TRUE", plot the estimated pfp vs the rank of each gene
rand	if specified, the random number generator will be put in a reproducible state
huge	if "TRUE" not all the outputs are evaluated in order to save space

### Value

A summary of the results obtained by the Rank Product method.

pfp	estimated percentage of false positive predictions (pfp), both considering upregulated and downregulated genes
pval	estimated pvalues per each gene being up- and down-regulated
RPs	the Rank Product statistics evaluated per each gene
RPrank	rank of the Rank Product of each gene in ascending order
Orirank	ranks obtained when considering each possible pairing. In this version of the package, this is not used to compute Rank Product (or Rank Sum), but it is kept for backward compatibility
AveFC	fold changes of average expressions (class1/class2). log fold-change if data has been log transformed, original fold change otherwise
allrank1	fold change of class 1/class 2 under each origin. log fold-change if data has been log transformed, original fold change otherwise
allrank2	fold change of class 2/class 1 under each origin. log fold-change if data has been log transformed, original fold change otherwise
nrep	total number of replicates
groups	vector of labels (as cl)

### Note

Percentage of false prediction (pfp), in theory, is equivalent of false discovery rate (FDR), and it is possible to be large than 1.

The function looks for up- and down-regulated genes in two separate steps, thus two pfps are computed and used to identify gene that belong to each group. The function is able to replace function RP in the same library. It is a more general version, as it is able to handle data from different origins.

RSadvance

*Advanced Rank Sum Analysis*

---

## Description

The function performs the Rank Sum method to identify differentially expressed genes. It is possible to do either a one-class or two-class analysis. It is also possible to combine data from different studies (e.g. datasets generated by different laboratories. This function has been kept only to guarantee backward compatibility, in fact the same results can be obtained by [RankProducts](#).

**Usage**

```
RSadvance(data, cl, origin, num.perm = 100, logged = TRUE, na.rm = TRUE,
gene.names = NULL, plot = FALSE, rand = NULL, huge = FALSE, fast = TRUE,
tail.time = 0.05)
```

**Arguments**

<code>data</code>	the data set that should be analyzed. Every row of this dataset must correspond to a gene
<code>cl</code>	a vector containing the class labels of the samples. In the two class unpaired case, the label of a sample is either 0 (e.g., control group) or 1 (e.g., case group). For one class data, the label for each sample should be 1
<code>origin</code>	a vector containing the origin labels of the samples. The label is the same for samples within one lab and different for samples from different labs.
<code>num.perm</code>	in this version of the package, this parameter is not used any more, but it is kept for backward compatibility
<code>logged</code>	if "TRUE" data have been previously log transformed. Otherwise it should be set as "FALSE"
<code>na.rm</code>	if "FALSE", the NA value will not be used in computing rank. If "TRUE" (default), the missing values will be replaced by the genewise median of the non-missing values. Gene with a number of missing values greater than 50% are still not considered in the analysis
<code>gene.names</code>	if "NULL", no gene name will be attached to the outputs, otherwise it contains the vector of gene names
<code>plot</code>	if "TRUE", plot the estimated pfp vs the rank of each gene
<code>rand</code>	if specified, the random number generator will be put in a reproducible state
<code>huge</code>	if "TRUE" not all the outputs are evaluated in order to save space
<code>fast</code>	if "FALSE" the exact p-values for the Rank Sum are evaluated for any size of the dataset. Otherwise (default), if the size of the dataset is too big, only the p-values that can be computed in "tail.time" minutes (starting from the tail) are evaluated with the exact method. The others are estimated with the Gaussian approximation. If calculateProduct="TRUE" this parameter is ignored
<code>tail.time</code>	the time (default 0.05 min) dedicated to evaluate the exact p-values for the Rank Sum. If calculateProduct="TRUE" this parameter is ignored

**Value**

A result of identifying differentially expressed genes between two classes. The identification consists of two parts, the identification of up-regulated and down-regulated genes in class 2 compared to class 1, respectively.

<code>pfp</code>	Estimated percentage of false positive predictions (pfp) up to the position of each gene under two identification each
<code>pval</code>	Estimated pvalues for each gene being up- and down-regulated
<code>RSs</code>	Rank-sum (average rank) of each genes
<code>RSrank</code>	Rank of the rank sum of each gene in ascending order
<code>Orirank</code>	Ranks in each possible pairing, in this version of the function this is not used to compute rank sum. It is here only for backward compatibility

AveFC	Fold change of average expression under class 1 over that under class 2, if multiple origin, than averaged across all origin. Log-fold change if data is in log scaled, original fold change if data is unlogged
allrank1	Fold change of class 1/class 2 under each origin. Log-fold change if data is in log scaled
allrank2	Fold change of class 2/class 1 under each origin. Log-fold change if data is in log scaled
nrep	Total number of replicates considering all the different origins
groups	Vector of labels (as cl).

### Note

Percentage of false prediction (pfp), in theory, is equivalent of false discovery rate (FDR), and it is possible to be large than 1.

The function looks for up- and down- regulated genes in two separate steps, thus two pfps are computed and used to identify gene that belong to each group.

The function is able to deal with single or multiple-origin studies. It is similar to function RP.advance expect a rank sum is computed instead of rank product. This method is more sensitive to individual rank values, while rank product is more robust to outliers (refer RankProd vignette for details)

### Examples

```
#Suppose we want to check the consistence of the data
#sets generated in two different
#labs. For example, we would look for genes that were \
# measured to be up-regulated in
#class 2 at lab 1, but down-regulated in class 2 at lab 2.\
data(arab)
arab.cl2 <- arab.cl

arab.cl2[arab.cl==0 & arab.origin==2] <- 1

arab.cl2[arab.cl==1 & arab.origin==2] <- 0

arab.cl2
##[1] 0 0 0 1 1 1 1 1 0 0
```

```
#look for genes differentially expressed
#between hypothetical class 1 and 2
arab.sub=arab[1:500,] ##using subset for fast computation
arab.gnames.sub=arab.gnames[1:500]
Rsum.adv.out <- RSadvance(arab.sub,arab.cl2,arab.origin,
                        num.perm=100,logged=TRUE,
                        gene.names=arab.gnames.sub,rand=123)

attributes(Rsum.adv.out)
```

topGene

*topGene*

## Description

Identify differentially expressed genes using rank product method

## Usage

```
topGene(x,cutoff=NULL,method="pfp",num.gene=NULL,logged=TRUE,
        logbase=2,gene.names=NULL)
```

## Arguments

x	the value returned by function RP, RPadvance, RSadvance, RankProducts or RP.advance
cutoff	The pfp threshold value used to select genes
method	if cutoff is provided, the method needs to be selected to identify genes. "pfp" uses percentage of false prediction, which is a default setting. "pval" uses p-values which is less stringent than pfp
logged	if "TRUE", data has been logged, otherwise set it to "FALSE"
logbase	base used when taking log, used to restore the fold change. The default value is 2, this will be ignored if logged=FALSE
gene.names	if "NULL", no gene name will be attached to the output table
num.gene	number of candidate genes of interests, if cutoff is provided, this will be ignored

## Value

Two tables of identified genes with gene.index: index of gene in the original data set RP/Rsum: Computed rank product/sum for each gene FC:(class1/class2): Expression Fold change of class 1/class 2. pfp: estimated pfp for each gene if the gene is used as cutoff point P.value: estimated p-value for each gene Table 1 list genes that are up-regulated under class 2, Table 2 list genes that are down-regulated under class 2
